

# Current State - No control

- Region 4 reaches  $\approx 110$  veh/km  $\rightarrow$  flow collapses  $\rightarrow$  “Gridlock”
- Average journey time  $> 1$  h.
- Long waiting time: 45 min
- No anticipation of future traffic

*Traffic flow with no control leads to gridlock, marked in red.*

# Failure mode - P controller

- P-controller reduces journey time by 20% yet can't handle late-rush surge.
- Single-region feedback ignores upstream queues.
- Same speed factor broadcast to all five roads → sub-optimal.

**A drastic reduction in CO2 emissions and travel time can be achieved with a new controller**

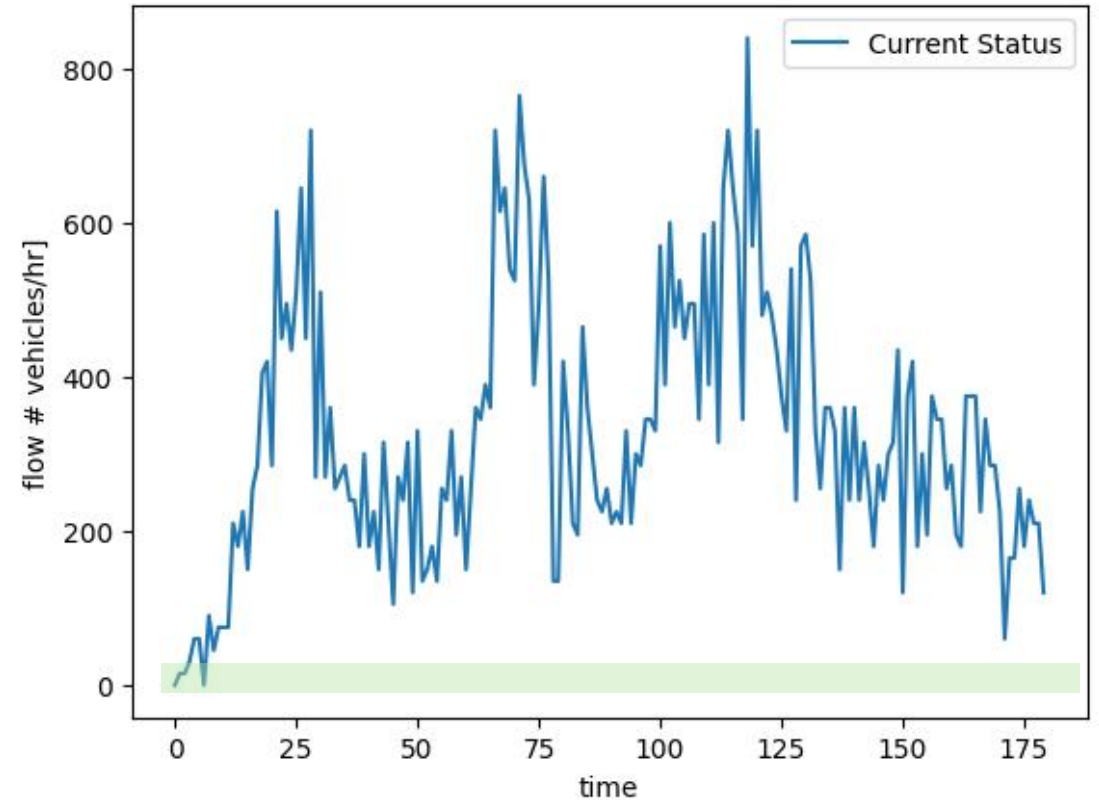

*Traffic flow with P-control still leads to gridlock, marked in red.*

# MPC

## *Model Predictive Control*

- Predictable behaviour
- Easy to follow DSL changes
- Can anticipate future traffic

*Traffic flows freely without gridlock using the MPC controller*

Avg travel time -72.5 % • 100 % trips completed

# TPC

## *Transient Predictive Control*

- Can deal with closed loop training data
- Fast compilation time
- Fastest average travel time

*TPC makes accurate density predictions*

*Traffic flows freely without gridlock using the TPC controller*

Avg travel time -80 % • Solves  $\approx 3\times$  faster than MPC

# Deployment

## Implementation

Phase	Model-based MPC	Data-driven TPC
<b>1. Offline preparation</b>	<ul style="list-style-type: none"> <li>Identify real world model and linearize around operating point</li> </ul>	<ul style="list-style-type: none"> <li>Collect 1-2 weeks of DSL commands, densities and flows from the real network (excite each road a bit to cover the dynamics).</li> </ul>
<b>2. Implementation</b>	<ul style="list-style-type: none"> <li>Implement hardware to run the controller</li> <li>Include a Kalman or moving-average state estimator to filter sensor noise.</li> </ul>	<ul style="list-style-type: none"> <li>Implement hardware to run the controller</li> <li>No explicit state estimator—uses raw measured inputs/outputs.</li> </ul>
<b>3. Monitoring &amp; updates</b>	<ul style="list-style-type: none"> <li>Re-identify model yearly or after major roadworks</li> <li>Retune parameters if traffic patterns shift.</li> </ul>	<ul style="list-style-type: none"> <li>Retrain predictors monthly with the newest data.</li> <li>No manual gain retuning needed in most cases.</li> </ul>

## Trade-offs

Aspect	Model-based MPC	Data-driven TPC
<b>Up-front effort</b>	Needs a trustworthy physics-based model and calibration → more engineering hours.	Minimal modelling; biggest cost is gathering representative data.
<b>Transparency &amp; verification</b>	High: linear model + quadratic cost allow formal proofs of stability and constraint satisfaction.	Medium-high: predictors are linear and inspectable but still data-driven.
<b>Adaptability to network changes</b>	Requires revisiting the model and gains after structural changes.	Simply collect new data and retrain; quick to port to other corridors.
<b>Robustness to unseen scenarios</b>	Good if the model covers the operating envelope; brittle outside it.	Same risk as any data-driven method: edge-case behaviour may be unknown

# Bonus: DeePC

## *Data-enabled Predictive Control*

- Better at capturing complex behaviour
- Uses real SUMO data—no model mismatch.
- More complex DSL changes
- More parameters to tune, requiring extra expertise

*DSL changes may be more challenging for human drivers.*

Avg travel time -74 % • Solves  $\approx 2\times$  faster than MPC

*Traffic flows freely without gridlock using the DeePC controller*
